Optical Properties of Solids (Oxford Master Series in Physics) By Mark Fox

The second edition of this successful textbook provides an up-to-date account of the optical physics of solid state materials. The basic principles of absorption, reflection, luminescence, and light scattering are covered for a wide range of materials, including insulators, semiconductors and metals. The text starts with a review of classical optics, and then moves on to the treatment of optical transition rates by quantum theory. In addition to the traditional discussion of crystalline materials, glasses and molecular solids are also covered.

The first edition included a number of subjects that are not normally covered in standard texts, notably semiconductor quantum wells, molecular materials, vibronic solid state lasers, and nonlinear optics. The basic structure of the second edition is unchanged, but all of the chapters have been updated and improved. Futhermore, a number of important new topics have been added, including:

- · Optical control of spin
- \cdot Quantum dots
- · Plasmonics
- · Negative refraction
- · Carbon nanostructures (graphene, nanotubes and fullerenes)
- \cdot NV centres in diamond

The text is aimed at final year undergraduates, masters students and researchers. It is mainly written for physicists, but might also be useful for electrical engineers, materials scientists and physical chemists. The topics are written in a clear tutorial style with worked examples, chapter summaries and exercises. A solutions manual is available on request for instructors.

Editorial Review

Review

"Fox's book provides an introduction to the subject for a senior-level undergraduate or a beginning graduate course aimed at students who will use or design equipment that depends on modern optical materials. . . . Fox, on the other hand, provides many well-selected examples, showing graphs of the actual dielectric functions associated with solids of technological intent. . . . Fox provides all that one could ask for in an undergraduate text. He describes many of the key devices for the technologies, including laser media based on Ti:sapphire (used for short pulses), gallium arsenide (for high continuous power), and Er:glass (for fiber-optics amplifiers. . . . While straightforward, Fox's problems offer an excellent way for the reader to test his understanding of the materials presented. . . . On the whole, fox has succeeded in offering a good, compact, senior-level presentation of the optical properties of solids." -- *American Journal of Physics*

"[A] useful and sound introduction to the subject."--Materials World
